

Post endodontic treatment periodontal surgery: a short case report

Abstract

Two patients were diagnosed with combined endodontic-periodontal lesions. First endodontic treatment of the respective teeth was performed, followed by surgery. In addition, the regeneration process was supported by the application of Emdogain alone or in combination with guided bone regeneration techniques. At recall visits after 24 months, in both patients the teeth were asymptomatic, and marked bone regeneration had occurred. The aim was to present the successful post endodontic treatment of combined endodontic-periodontal lesions, using periodontal surgery and as adjunct guided tissue regenerative techniques.

Key Words: Periodontal-endodontic lesion, root canal treatment, surgery.
